Registration application 1: deformation-based morphometry

template
(vs. individual)
Jacobian

individual
(vs. template)
Jacobian

Avants, et al. 2008

Jacobian matrix: representation of a differential, an $n \times n$ matrix of first order partial derivatives whose entry in the i -th row and j -th column is $\partial f_i / \partial x_j$. The Jacobian can be thought of as describing the amount of "stretching" that a transformation imposes.

Registration application 2: anatomical localization

Registration application 3: group analysis of data

data (structure, function, physiology, landmarks) in individual space

individuals normalized to template space

Registration application 3: group analysis of data

data (structure, function, physiology, landmarks) in individual space

Registration application 4: atlas-based anatomical labeling

Registration application 4: atlas-based anatomical labeling

Registration applications

What characterizes a registration algorithm?

Similarity metric:	SSD, MSD, (n)CR, (n)CC, MI,...
Transformation:	affine, piecewise linear, nonlinear,...
Regularization:	multi-resolution/scale, Gaussian blur,...
Optimization:	simplex, gradient descent,...
Interpolation:	nearest-neighbor, trilinear, cubic, sinc,...

Nonlinear registration example

local translations, free-form deformations

optimization of 3 translational parameters
to maximize the neighborhood cross-
correlation for each node (ANIMAL)

Nonlinear registration example

topological constraints: diffeomorphisms

homeomorphism: continuous mapping and inverse, but not deformation (trefoil knot, circle)

diffeomorphism: bijective map from manifold M to N and its inverse are differentiable

“Evaluation of 14 nonlinear deformation algorithms applied to human brain MRI registration”

Participants: 16 from 11 institutions

Algorithms: >14 software packages

Data: 80 brains manually labeled according to 4 different

Registrations: whole-brain labeling protocols (56 to 128 regions)

Evaluation:

Analysis: Each algorithm applied >2,168 times (>45,000 total)

8 measures (overlap, distance, volume

Analysis

Statistical tests run on small sets of independent samples:

Permutation tests

One-way ANOVA tests

Ranking based on practical significance (volume offset):

Indifference-zone ranking

Results

target overlap averaged across all registrations (LPBA40)

SPM_N*="SPM2-type" Normalize
SPM_N=Normalize
SPM_US=Unified Segmentation
SPM_D=DARTEL pairwise

Results: Indifference-zone ranking

Indifference-zone ranking

Each color cell represents the average score for a given region and for a given algorithm, averaged over 1,560 LPBA40 registrations.

Blue indicates higher accuracy.

The scores are $\{-1, 0, 1\}$ values indicating the pairwise performance of the algorithm relative to each of the other methods, according to target volume overlap.

SPM_N*="SPM2-type" Normalize
 SPM_N=Normalize
 SPM_US=Unified Segmentation
 SPM_D=DARTEL pairwise

Indifference-zone ranking

Indifference-zone ranking of the registration methods by label set. This table lists the methods that attained the top three ranks after averaging scores across all brain regions then across all registration pairs (μ =mean, SD=standard deviation). The scores reflect a pairwise comparison between methods, according to target overlap. Methods within ranks 1, 2, and 3 have positive means lying within one, two, and three standard deviations of the highest mean, respectively. Values are not comparable across label sets (columns). (SPM_D=DARTEL pairwise)

Permutation ranking

	LPBA40	μ (SD)	IBSR18	μ (SD)	CUMC12	μ (SD)	MGH10	μ (SD)

					JRD-fluid	.17 (.81)		

Permutation test ranking of the registration methods by label set. This table lists the methods that attained the top three ranks after conducting permutation tests between mean target overlaps (averaged across regions) for each pair of methods, then calculating the percentage of p-values less than or equal to 0.05 (of 100,000 tests for CUMC12 and MGH10 or of 10,000 tests for LPBA40 and IBSR18; μ =mean, SD=standard deviation). Methods within ranks 1, 2, and 3 have positive mean percentages lying within one, two, and three standard deviations of the highest mean, respectively. Values are not comparable across label sets (columns). (SPM_D=DARTEL pairwise)

Average ranks

DARTEL Toolbox (pairs)		Matlab 7.0 onwards	Analyze, NiFTI	left-handed orientation origin near anterior commissure	71.8 (6.3)*

Evaluation

distance

Average distance error = the minimum distance from each source region boundary point, $S_r B_p$, to the set of points making up the target region boundary, $T_r B$, averaged across P points:

$$DE_r = \frac{1}{P} \sum_{p=1}^P \text{mindist}(S_r B_p, T_r B)$$

Analysis

permutation tests

1. Select a subset of P independent brain pairs
2. Select a pair of methods (two vectors of P total overlap values)
3. Subtract the two vectors and compute the mean difference D
4. Select a subset of the elements from one of the vectors
5. Swap this subset across the two vectors
6. Subtract the resulting vectors; compute the mean difference D_p
7. Repeat steps #4-6 N times
8. Count the number of times n where⁴ $\text{abs}(D_p) \geq \text{abs}(D)$
9. Compute the exact p-value: $p = \frac{n}{N}$
10. Repeat steps #1-9; compute the fraction of times where $p \leq 0.05$

Analysis

One-way ANOVA tests

We also performed a standard one-way ANOVA to test if the means of similar subsets of independent average target overlap values obtained by each of the registration methods are the same. We then subjected these results to a multiple comparison test using Bonferroni correction to determine which pairs of means are significantly different (disjoint 95% confidence intervals about the means, based on critical values from the t distribution). We repeated these ANOVA and multiple comparison tests 20 times, each time randomly selecting independent samples from each of the datasets. These tests are not expected to be as accurate as the permutation tests because some of the overlap values have skew distributions and because the p-values are not exact.

Analysis

Indifference-zone ranking

Our third evaluation between methods tested practical significance rather than statistical significance. For example, if a region is registered to another region of equal volume and results in an offset of a single voxel, this is not considered a significant misregistration, but offsets greater than this are considered significant. An evaluation measure of registration accuracy for a given region within a given brain pair is calculated for two different registration methods. If these two values are within delta of one another (referred to as an “indifference zone” when ranking (Bechhofer, 1954)), they are considered equal. The delta must correspond to a practical difference in registration. If we model a region as a cube, then a single-voxel offset along the normal to one of its faces would mean the voxels on that face of the cube reside outside of its target – this is equal to one-sixth of its surface. We therefore set delta to one-sixth of a target region’s surface. For the IBSR18, CUMC12, and MGH10 datasets, we assumed the surface to be that of a cube ($6 \times edge^2 - 12 \times edge$, where $edge$ = the edge length of a cube with the volume of the target region, in voxels). For the LPBA40 dataset, we set the surface to the number of voxels bordering adjacent regions.
